Abstract. We present new observations of 11 symbiotic and symbiotic-like stars. The photoelectric UBV(R) observations described here cover the period spanning from 1994.75 to 1996.0. Some CCD VRI and photographic data were obtained also during the earlier times. The main results obtained during this campaign period can be summarized as follows:

Z And: The UBV light curves (LC) indicate a small brightening of the star around JD 2 449 750. EG And: Standard phase dependent behaviour – an increase in the star's brightness from orbital phase $\varphi \sim 0$ (around JD 2 449 700) to $\varphi \sim 0.7$ (\sim JD 2 450 050) – is apparent in our light curves. UV Aur: Two \sim 390-day cycles were covered by our observations. Variations in the V and R bands are similar. TX CVn: Very slow brightness decline from the previous active stage has continued during the present period. BF Cyg: A minimum around JD 2 449 900 was observed – in agreement with the ephemeris given by Pucinskas (1970). CH Cyg: During the period Oct. 15th 1994 – Jan 16th 1995 a minimum corresponding to the eclipse of the hot component by the red giant occurred. The sudden fading of the star in the U and B colours suggests that the 1992 outburst is over. AG Dra: The present data cover a major part of the recent (1994) outburst. A second maximum has been observed during

Contrib. Astron. Obs. Skalnaté Pleso **26**, (1996), 46– 64.

the summer of 1995. Afterwards, the system's brightness has been declining towards the quiescence.

Key words: stars – binaries – symbiotic – symbiotic-like – photometry

1. Introduction

This is the first part of the seventh paper of the series aimed at the presentation of the observational data compiled as a part of the campaign of long-term photometry of symbiotic stars (Hric & Skopal, 1989). The division of this paper into two parts resulted from the large amount of the material presented. The editor of the CAOSP journal has thus recommended us to adopt such a solution. The previous results of our observational campaign were published in Skopal et al., 1990 - Paper I, Hric et al., 1991 - Paper II, Skopal et al., 1992 - Paper III, Hric et al., 1993 - Paper IV, Hric et al., 1994 - Paper V, Skopal et al., 1995 - Paper VI.

2. Observations

Photoelectric UBV(R) observations were performed at the Skalnaté Pleso Observatory (hereafter SP in Tables), at the Stará Lesná Observatory (SL), at the Hlohovec Observatory (H), at the Kryonerion Station of the National Observatory of Athens (KN – observer Niarchos, KR – observer Rovithis) and at the N. Copernicus Observatory and Planetarium in Brno (B1). The observations carried out at the Skalnaté Pleso Observatory, at the Stará Lesná Observatory, at the Kryonerion Station of the National Observatory of Athens, at the Hlohovec Observatory and at the Brno Observatory were performed in the same way as described in Paper II, III and VI.

New photoelectric observations were obtained during the normal campaign period between October 1, 1994 and December 31, 1995 but numerous earlier observations were included.

All the CCD observations were performed at the Považská Bystrica Observatory (PB) with the Newton 180/700 telescope equipped with an originally constructed CCD camera based on Texas Instruments chip TC 211 and using V (540 nm), R (680 nm), I (825 nm) filters for modified Johnson-Kron-Cousins system. The magnitudes of the comparison stars for CCD photometry were obtained through the calibration on the basis of the standard stars published in Landolt (1973, 1983, 1992).

Photographic observations at the Trnava Observatory (T) were obtained by the Sonnar 4/300 equipped by filter Panchromar G3 on the emulsion OR-WOPAN 400. This combination of filter and emulsion enables to cover spectral region from 570 to 650 nm.

3. Results

The photoelectric UBVR data for all the observed objects have been summarized in tables. The data were displayed in figures in those cases when the stars involved exhibited some kind of interesting behavior or, especially for the visual photometry, the data represented sufficiently extensive collection of observations. Individual stars are arranged in alphabetic order and the relevant results are briefly discussed in subsections.

3.1. Z Andromedae

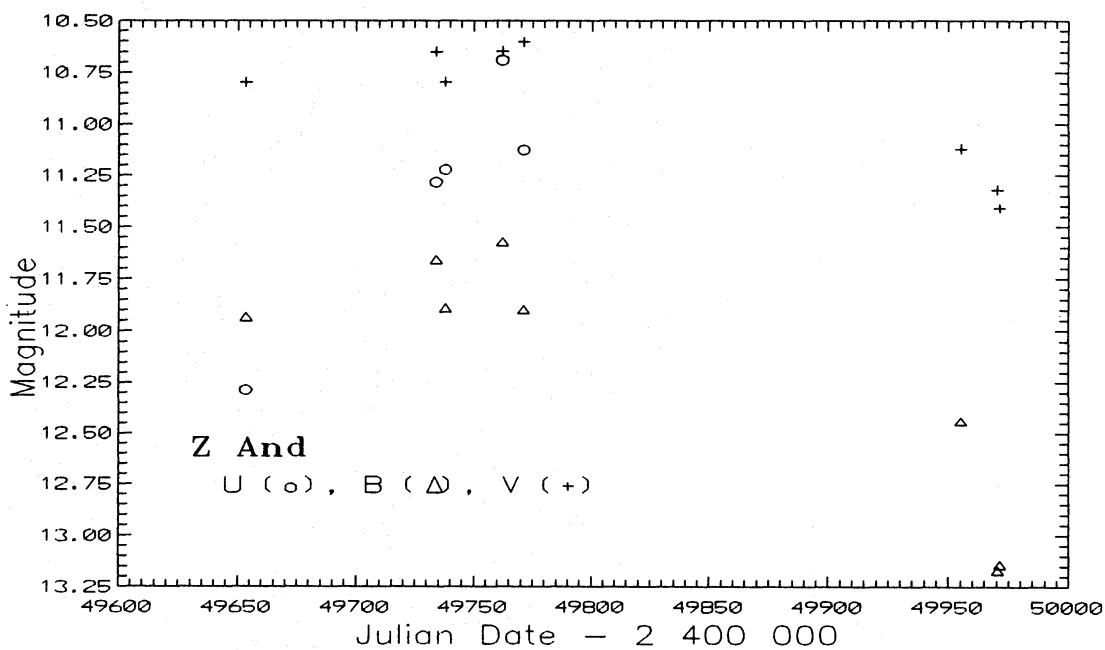

Figure 1. UBV observations of Z And.

Z And was observed photoelectrically on 8 nights. The standard stars are the same as used in Paper II. The data are presented in Table 1 and shown in Figure 1. The LC displays small brightening around JD 2 449 750. The visual LC depicted in Figure 2 is in a very good agreement with such behaviour. This indicates that the star is still in a quiet stage.

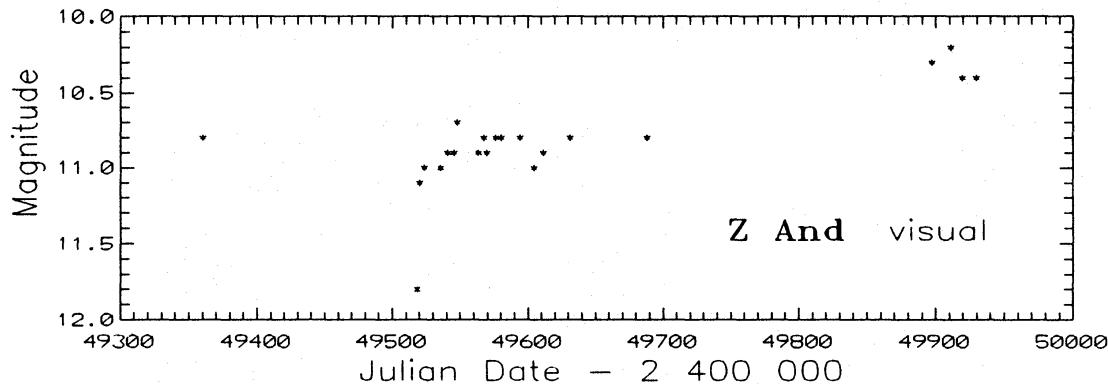

Figure 2. Visual observations of Z And.

3.2. EG Andromedae

The UBV(R) photoelectric observations were carried out during 29 nights. The comparison stars S_1, S_2, S_3 are the same as used in the Paper II, and S_4 as in the Paper III. The UBVR data are compiled in Table 2 containing the differential

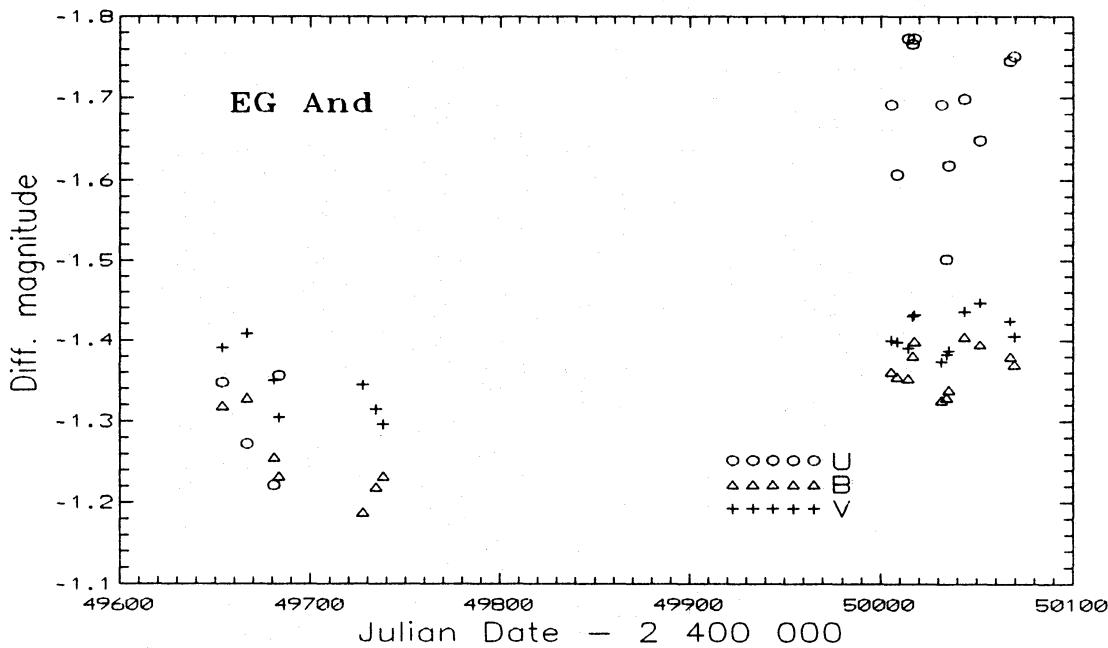

Figure 3. UBV Observations of EG And

magnitudes. The UBV observations are depicted in Figure 3 and visual estimates are shown in Figure 4.

3.4. UV Aurigae

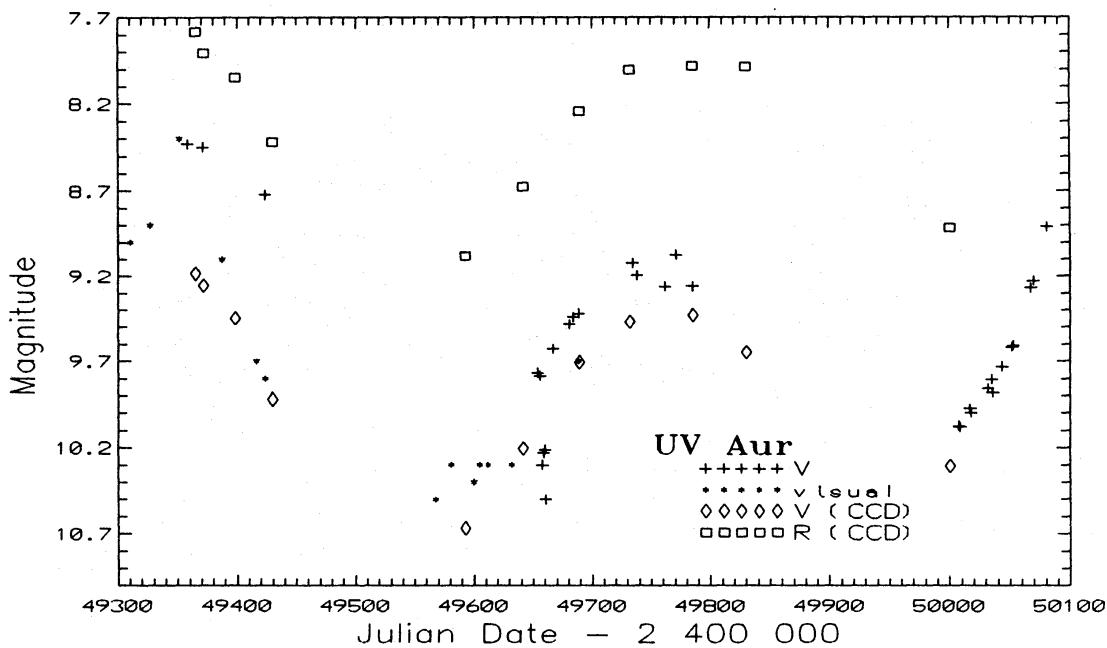

The photoelectric UBVR, CCD VRI and photographic photometry of this star was obtained on 42 nights. The results are summarized in Tables 4 and 5. The data in selected colours (VR photoelectric, VR CCD and visual estimates) are depicted in Figure 5. The LC shows variations in all colours which correspond to two cycles of the basic period. The amplitude of sinusoidal variations in R colour has almost the same value as in V filter. The period analysis of the data confirms the same changes of the periodicity of the brightness variations we have mentioned in the previous campaign paper (Paper VI).

3.5. TX Canum Venaticorum

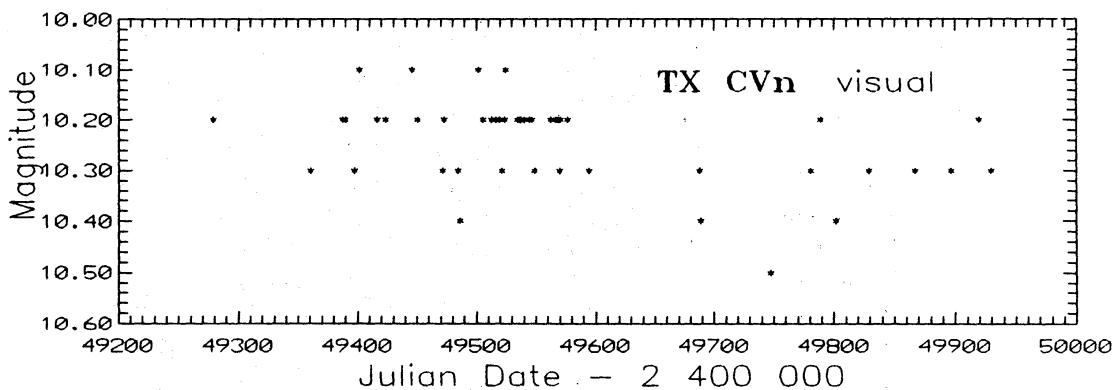

Both UBV(R) photoelectric and visual observations have been obtained for this star. The data covering the period of almost 2 years are shown in Figure 6. On the basis of the visual LC presented here as well as of the relevant LCs published in the previous campaign paper (Paper VI), we can see very slow decline of brightness from an active stage.

3.6. T Coronae Borealis

The photoelectric data obtained for this star are presented in Table 7. The visual observations are depicted in Figure 7. The LC is in a good agreement with the following ephemeris: $JD_{min} = 2435\,571 + 227.8 \times E$ (Paper II).

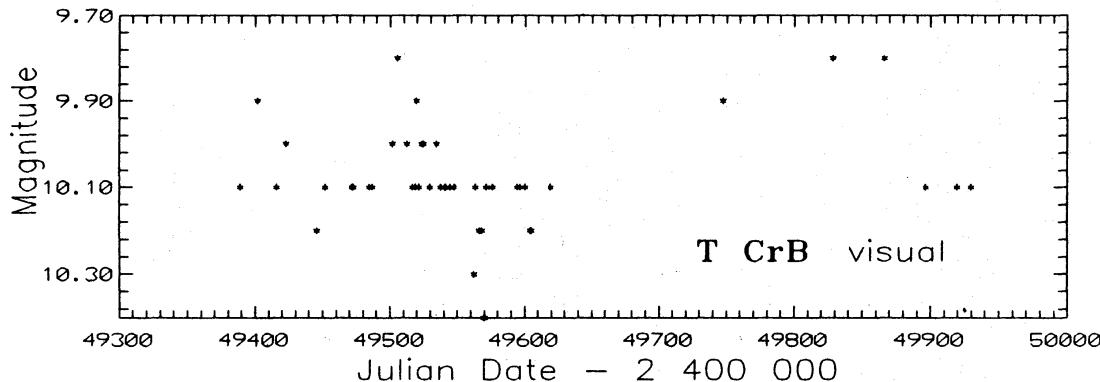

Figure 7. Visual Observations of T CrB

3.7. BF Cygni

The photoelectric measurements of this star were performed on 14 nights. The same standard stars were used as in Paper III. The results of UBVR photometry are compiled in Table 8. The UBV data are depicted in Figure 8. Our data indicate a minimum around JD 2449900 whose position agrees well with the ephemeris for the photometric minima suggested by Pucinskas (1970): $\text{Min} = 2415065 + 757.3 \times E$.

3.8. CH Cygni

**Figure 9. UVBR Observations of CH Cyg**

The UBVR photoelectric observations of this star were obtained in 68 nights. The star HD 182691 (SAO 31623; $V = 6.525$, $B - V = -0.078$, $U - B = -0.24$, $V - R$

Δ = 0.00, spectrum B9) was used as the basic comparison. The other standard stars are the same as in Papers II and III. The results are compiled in Table 9 and shown in Figure 9. The U data in this figure were connected by solid line in order to distinguish them from the B data which show similar course (we use this approach also in the case of PU Vul). During the period Oct. 15th 1994 – Jan. 16th 1995, a minimum corresponding to the eclipse of the hot component by the red giant in the symbiotic pair of the triple CH Cyg system occurred (see Skopal et al., 1996 for more details). The star's brightness in the U and B bands suddenly faded around JD 2449880, indicating thus that the 1992 outburst of CH Cyg is over.

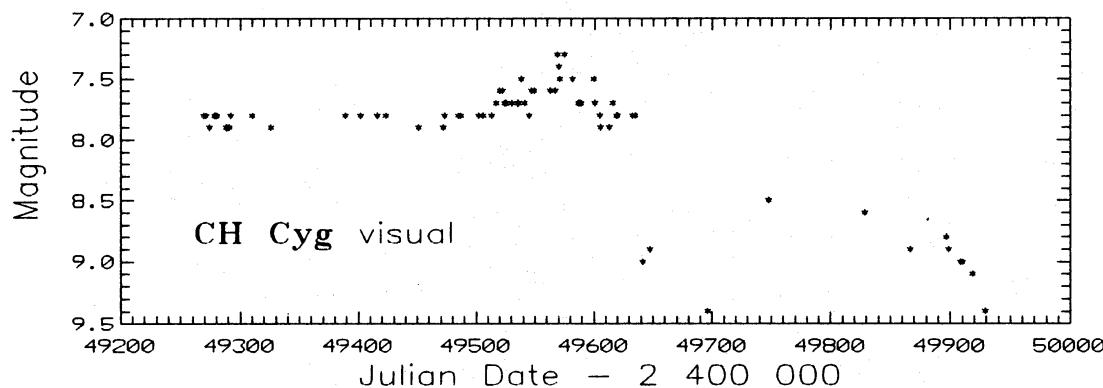

The visual observations are shown in Figure 10. The minimum observed around JD 2449700 is in accord with the UBV data.

**Figure 10.** Visual observations of CH Cyg

3.9. V 1016 Cygni

The UBVR photoelectric observations of this star were carried out on 16 nights. The standard stars are the same as in Paper III. The results are compiled in Table 10 and depicted in Figure 11. There are no significant changes in U,B,V and R colour in the LC.

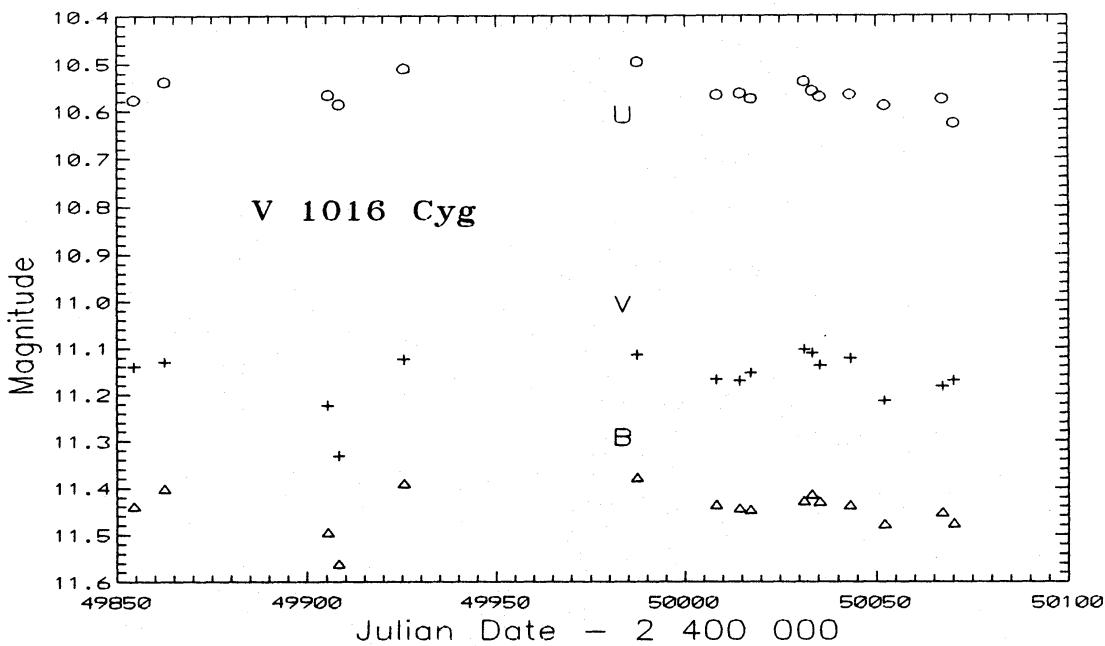

Figure 11. UBV Observations of V 1016 Cyg

3.10. V 1329 Cygni

The VRI CCD photometric data for this star were obtained only in 3 nights. The results are compiled in Table 11. The brightness of the star increased in agreement with the following ephemeris derived by Hric et al. (1993): $JD_{min} = 2446\,784.862 (\pm 2.4) + 963^d.306 (\pm 0.772)E$.

Table 11. VRI observations of V 1329 Cyg

50000.363	13.486	11.572	10.400	PB

3.11. AG Draconis

The UBVR photoelectric observations of this star were performed in 70 nights. The standard stars are the same as in Paper II. The results are compiled in Table 12. The U, B and V data are shown in Figure 12. The observations presented here cover a major part of the recent (1994) outburst of AG Dra. The second maximum occurred during the summer of 1995 in accordance with the prediction made by Skopal and Chochol (1994). Behaviour in the UBV light curves

after \sim JD 2 450 000 indicates that the system gradually declines to quiescence.
