**Abstract.** The daily soft X-ray flare index was determined from the daily continuous profile of solar soft X-ray flux. In order to determine the heliographic coordinates of Long Duration Events (LDEs) we exploited the fact that the soft X-ray flare emission is uniquely tied with the occurrence of H-alpha flares. The daily flare index is given in Tables 1 and 2. They contain the Eastern (E), Central (C) and Western (W) indices of an LDE as well as a daily flare index of the impulsive (I) flares, observed from January 1969 to December 1972.

**Key words:** the Sun - flares

## 1. Introduction

The properties of a solar soft X-ray component indicate the existence of dense thermal plasma located in the corona as it can be discerned from the daily solar soft X-ray flux (1-8 Å), which is sensitive to the coronal emission measure at temperatures  $T \geq 3 \times 10^6$  K (Donnelly et al. 1977). The daily variations of the flux give us, however, information not only about changes in the corona, but tell us also something about short-term variations in the heliosphere.

Our subsequent reasoning is based on the solar daily soft X-ray flux data (1969-1976) published in *Solar Geophysical Data* and on those by Donnelly (1981). The unresolved full-sun soft X-ray flux measurements provide us with the information about both (i) a nonflare coronal background (XBG flux, Bouwer et al. 1982) and (ii) a flare emission, which can be detected as soft X-ray emission peaks above an XBG level.

The present paper gives a brief account of the 1-8 Å flare emission. A detailed description of the soft X-ray measurements is given in Section 2. Section 3 contains the new definition of the flare index and our findings are compared with those based on the old definition (1990-1994 papers). Tables 1 and 2 and their descriptions are given in Section 4. The discussion of the implications of short-term soft X-ray activity in the context of heliospherical environment is given in Section 5.

## 2. The soft X-ray measurements (1969-1976)

The full-sun soft X-ray daily profile is published in SGD, being constructed from the 1-5 minute means obtained from the following satellites:

Satellite	Time interval
SOLRAD 9:	January 1969-February 1973
EXPLORER 37:	February 1973-April 1974
SMS-1, SMS-2 and GOES-1:	July 1974-December 1976

The missing soft X-ray data between *May-June 1974* were supplied from (i) the daily mean 10.7 cm radio emission (2.84 GHz), which is well correlated with SXR (Donnelly et al. 1986), as well as ii) from the existence of Sudden Ionospheric Disturbances (SIDs - which are sensitive to an SXR flux). The list of SIDs was compared with that of H-alpha flares as published in SGD.

## 3. Definition of the flare index

The flare index (FI) was constructed by weighing the SXR flare-classes (in units of  $10^{-6} \text{ W/m}^2$ ) regardless the duration of a flare. For the convenience of the reader we list all soft X-ray flare classes our paper is based on:

Class	Flare-Intensity ( $\text{W/ m}^2$ )
C	$10^{-6} \leq I < 10^{-5}$
M	$10^{-5} \leq I < 10^{-4}$
X	$I \geq 10^{-4}$

Digits from 1.0 to 9.9 following the above letters act as multipliers.

As for the so called Long Duration Event (LDE) flare index, the corresponding analysis was carried out either on the monthly basis (Antalová, 1990; Antalová and Viktorínová, 1991) or on the half-monthly basis (Kudela et al. 1994). It is worth recalling at this point that the LDE-type FI ascribes null weight for events lasting less than 2 hours, and single weight for long duration events lasting  $\geq 2$  hours (see, Antalová and Viktorínová (1991) for more details). Here we aim at bridging the 1990's LDE FI data gap by introducing:

- a flare index on the basis of complete SXR flare information, using not only a flare class, but also digit multipliers: so, for example, a C7.3 (M1.9, X9.6) soft X-ray flare index bears now the value equal 7 (19, 960), and not 1 (10, 100) as it would if we followed our old definition;
- a new daily flare index (I) is computed from impulsive-type soft X-ray flares (lasting less than 2 hours); and

- we publish daily, not monthly FI values, as the former are more suitable for a short-term solar activity analysis and related heliospherical problems.

## 4. Daily flare index values

### 4.1. The Types of soft X-ray flares and the process of magnetic reconnection

A classification of soft X-ray flares was first introduced by Pallavicini et al. (1977) and Kahler (1977). The duration of a flare in soft X-rays is very different from that characterizing both shorter and longer wave length flare emission in the sense that we can clearly distinguish between short and long duration flare categories, which is therefore taken as an important characteristic of soft X-ray flare. Although, starting from 1977, both the categories have been extensively studied there is still not clear answer where lies the boundary between them, nor what are the other physical characteristic (temperatures, chemical composition, etc.) exclusively pertinent to either category. We also note that this phenomenological 2-type soft X-ray flare classification is based on very different gradual phases of both flare categories. Both of them have a very similar onset, the so called 'impulsive phase', during which the proper flare energy is released. It is generally believed that the category of impulsive flares has the impulsive phase only, but lacks the gradual one.

The main source of a prolonged soft X-ray emission is a post-flare loop arcade, which is regarded as the symptom of the process of strong magnetic reconnection. In fact, the arcade is usually a remnant of outward opened magnetic structures during the impulsive phase of an LDE-type flare. So, this evokes a question: 'Why has the process of reconnection so different scales for two flares with a comparable impulsive phase?' It is difficult to answer this question satisfactorily, but in the case of impulsive flare it is obvious that the open magnetic configuration and the following process of reconnection have much smaller dimensions when compared with those characterizing an LDE-type flare.

### 4.2. LDE- and I-type flares and their consequences for heliosphere

- From our crosscorrelation analysis between the galactic cosmic ray (CR) intensity and nonflare coronal background (XBG) we found a significant anticorrelation between the daily values. So, the nonflare corona is best viewed as a slowly expanding solar wind source. The soft X-ray flux of long lasting, dense post-flare coronal sources is by an order of 1-4 higher than XBG and, therefore, its contribution to the solar wind cannot be neglected.
- The long lasting discussion about 'What can be used as the proxy data of Coronal Mass Ejections that are very difficult to observe and at that only at the 90° distance from the central meridian of Sun?' is still surviving (e.g., Harrison 1996). Our aim is to see which flare category is better CME related.

### 4.3. Description of the table

Having in mind all pros and cons, the daily flare index was computed separately for:

- (i) the LDE-type flare ( $\geq 2$  hours), which is identical with the flare-type known as a 'long decay' (Kahler, 1977) and related to an eruptive flare definition (Švestka, 1995),
- (ii) the impulsive-type flare (lasting in SXR less than 2 hours). From the table we see that the classification into C, E, and W belts is given only for LDE-type flares, because the I-type is so short-lasting that there are no corresponding  $H_{\alpha}$  data available.

The left (right) columns of Table 1 and Table 2 comprise the odd (even) year data. Tables 1 and 2 list the daily flare indices of the following flare subsets:

*E* - the daily flare index for LDE-type flares located from  $E90^{\circ}$  to  $E45^{\circ}$  on the solar disk;

*C* - the same as above but for LDE-type flares located from  $E44^{\circ}$  to  $W44^{\circ}$ ;

*W* - the same as above but for LDE-type flares located from  $W45^{\circ}$  to  $W90^{\circ}$ ;

*D* - the daily flare index of all LDE-type flares;

*I* - the impulsive-type daily flare index;

*T* - the daily flare index of all soft X-ray flares (total,  $T = D + I$ ).

## 5. Discussion

– *The daily flare index* has already been analysed in a series of our papers published since 1994 (e.g. Antalová et al. (1995); Storini et al. 1995; Antalová et al. 1996).

– *The East-West distribution* of the solar LDE-type flares was also considered in some of our previous papers (Storini et al. 1995 and Jakimiec et al. 1995). The main result is a greater delay for CRs–FI(E) crosscorrelation functions than for that of FI(C) and FI(W). However, it is worth mentioning that such different East-West delays were in the past obtained not only analysing galactic cosmic ray intensities, but also solar proton fluxes (e.g., Iucci et al. 1979, Sarris 1983, Sarris et al. 1984, Sarris et al. 1989). Moreover, a similar behaviour is emerging from multi-spacecraft measurements of CMEs (Reames 1994, Reames et al. 1996) through the interplanetary protons (accelerated by CME shock). This supports the hypothesis that the CME phenomenon is partly interrelated with some but not all of the LDE-type flares (Harrison 1996). This hypothesis is also in agreement with the results obtained from a direct comparison of 1986-year GOES SXR events with Coronal Mass Ejections (Burkepile et al. 1994).

**Table 1.** The 1969 (left) and 1970 (right) E-T columns of the daily values of soft X-ray flare indices
