Received: February 7, 1999

Abstract. The heliographic longitudinal distribution of the daily soft X-ray flare index values is given for 1979 and 1980 years (Table 1). The soft X-ray flare index was determined from the daily continuous SMS-GOES profile of solar soft X-ray flux (0.1–0.8 nm), as published in Solar Geophysical Data. The left (right) columns of Table 1 comprise the 1979 (1980) daily data. The Eastern (E), Central (C) and Western (W) LDE-type flare indices, as well as a daily flare index computed from the impulsive-type (I) flares were so far published for the decreasing part of the 20-th solar cycle, as well as for the onset part of the 21-st solar cycle (from January 1, 1969 to December 31, 1980).

Key words: the Sun - LDE type flares - impulsive flares - flare index (FI)

1. Spatial distribution of LDE-type flares

It was found that SXR flares, and in particular those of long duration, occur in connection with Coronal Mass ejections (CMEs, Kahler et al., 1989). The 1969–1978 daily SXR (0.1–0.8 nm) flare index has already been published (Antalová, 1996) in the Contributions of the Astronomical Observatory Skalnaté Pleso (Volumes 26, 27 and 28). This paper gives the 1979–1980 continuation of the daily flare indices (FIs). These FIs were constructed by weighing the SXR flare-classes (in units of 10^{-6} W/m^2) regardless the duration of a flare (Antalová, 1996). For example, the flare of GOES class C1.7, (M9.5; X12.3) has value of the SXR flare index equal to 2 (95; 1230). The LDE-type flare FI values are given into E-C-W heliographic belts and their sum represents the global value for the all solar disk (D). The left (right) columns of Table 1 comprise the 1979 (1980) daily SXR flare index, which was computed separately for: (i) the LDE-type flare (duration in SXR \geq 2hours), which is identical with the flare-type known as a 'long decay' (Kahler, 1977) and related to an eruptive flare definition (Švestka, 1995), Coronal Mass ejections (Webb et al. 1997) and geomagnetic storms (Bravo, 1997; Webb et al. 1998); (ii) the impulsive-type flare (lasting in SXR less than 2 hours). The distribution of FI into E, C, and W heliolongitudinal belts is given only for LDE-type flares. The following flare subsets are given in Table 1:

Contrib. Astron. Obs. Skalnaté Pleso **29**, (1999), 59–68.

Table 1. The 1979 (the left E-T columns) and 1980 (right) daily values of the soft X-ray (0.1–0.8 nm) flare indices. E-C-W columns give the FI distribution of LDE-type flares located into Eastern, Central and Western solar longitudinal belts.

E - the daily FI from LDE-type flares located between E90° and E45° on the solar disk;

C - the FI for LDE-type flares located from E44° to W44° on the Sun;

W - the same as above but for LDE-type flares located from W45° to W90°;

D - the soft X-ray flare index of all LDE-type flares observed in the given day;

I - the daily flare index of the impulsive-type flares;

T - the daily flare index of all soft X-ray flares (total, T = D + I).

Flares and CMEs appear to be often closely related (Dryer, 1996). The role of the coronal mass ejections (by using soft X ray solar emission as proxy data) in producing the nonrecurrent geomagnetic storms has been confirmed by Landi and Storini (1997) as well as Landi et al. (1998).
