Abstract. We present the $UBV(RI)_C$ photometry of a new dwarf nova V466 And, discovered during its superoutburst on Sept. 1.6, 2008 and classified as a WZ Sge-type object. In the first 11 days of the superoutburst, the early superhumps with the period of $0.^d056383$ were found. In days 13 – 23 of the superoutburst, the ordinary superhumps with the period of $0.^d05713$ were exposed. They were replaced by late superhumps with the period of $0.^d056$ in days 24 – 33 of the superoutburst. After one month, the dwarf nova returned to its pre-outburst state. A list of known WZ Sge-type dwarf novae, including suspected ones, is presented. We determined a mean value of superhump period excess for WZ Sge-type objects as $\epsilon=0.019\pm0.003$. The multicolour photometry of the field stars enables us to conclude that there is no appreciable interstellar extinction in the direction of V466 And.

Key words: dwarf novae – photometry, superoutburst, superhumps

1. Introduction

Dwarf novae (DNe) are a subclass of cataclysmic variable stars - semidetached binaries, consisting of a red dwarf, transferring matter to a white dwarf. Variability of DNe is caused by the orbital motion of the components and quasi-periodic outbursts resulting from instabilities in the accretion disk, surrounding the white dwarf. The SU UMa-type DNe exhibit short ($\sim$ days) normal outbursts and long ($\sim$weeks) less frequent superoutbursts. During superoutbursts, which are $\sim (1 – 3)$ mag brighter than normal outbursts, a unique feature develops: superhumps – brightness variations with the period of a few percents longer than the orbital one (see, e.g., Patterson & Warner, 1998).

The WZ Sge-type DNe are the most extreme subgroup of SU UMa-type DNe with a long (several years) superoutbursts recurrence time. Some of them exhibit a complex post-superoutburst rise of brightness called rebrightening(s), rarely seen in other SU UMa-type dwarf novae. One of the most remarkable signatures of WZ Sge-type objects is a presence of "early superhumps" during the earliest stages of their superoutbursts. This feature is also referred to as orbital superhumps or outburst orbital humps. Early superhumps have a period extremely close to the binary period and commonly show a double - humped profile, in contrast to the ordinary superhumps of SU UMa-type dwarf novae. Early superhumps are the most discriminative feature of the WZ Sge-type objects, and have not been detected in other DNe (Andronov et al., 2001; Kato et al., 2009a).

V466 And was discovered as an optical transient by K. Itagaki (Yamaoka et al., 2008) on a CCD image taken on September 1.6 UT (JD 2454711.1) with the 0.21m reflector in the course of his sky survey. A confirming unfiltered CCD image was taken with the 0.6-m reflector on Sept. 1.603, that yields ~ 12.7 mag and the following precise position: R.A. $= 2^h00^m25^s.40$, Decl. $= +44^o10'18".7$ (equinox 2000.0) (Yamaoka et al., 2008). V466 And has a GSC-II counterpart with R.A. $= 02^h00^m25^s.44$ and Decl. $= +44^o10'19".1$ (J2000) with the $j = 21.16$ mag.

Korotkiy, Kryachko and Satovskiy (see Korotkiy, 2008) confirmed a possible nova in Andromeda as an object ~ 12.45 mag, found in one unfiltered image taken on Sep. 1.834 UT at the Kazan State University Astrotel Observatory (Karachay-Cherkessia, Russia) with the 8.0-cm f/7.5 ED-refractor (+ SBIG ST-2000XM). Their photometric observations during JD 2454711.343 – 11.434 (Sept. 1.843 - 1.934) clearly showed a humped light curve with the amplitude of $0.^m13$ and period of $0.^d055(1)$, typical for cataclysmic variables of the WZ Sge-type.

The first multicolour photometry of the object was carried out by Shugarov and Volkov (2008) with the 0.6m reflector of the Astronomical Institute of the Slovak Academy of Sciences observatory in Stará Lesná, equipped with the photoelectric photometer, on Sept. 2.87 UT ($U = 12.29, B = 13.16, V = 13.15$) and Sept. 3.08, ($U = 12.28, B = 13.19, V = 13.09, R_J = 13.31$).

Challis et al. (2008) reported that the spectrum of the object, obtained with the 1.5m Tillinghast telescope of the Fred L. Whipple Observatory at Mt Hopkins on Sept. 3.479, is that of a dwarf nova in outburst.

Shafter et al. (2009) shortly presented the information about time-resolved CCD photometry of V466 And. During the nights Sept. 4 – 6, 2008, the object faded from $V = 13.4$ mag to $V = 14$ mag, and reached $V = 16.8$ mag on September 25, 2008. The data from the nights Sept. 4 – 6 revealed $V \sim 0.1$ mag dips in the light curve with recurrence time given by a best-fit period of 0.05636(9) days. They interpreted it as a manifestation of "early superhumps" of the WZ Sge-type system.

Kato et al. (2009a) used the VSNET data to derive the period of early superhumps of V466 And as 0.056365(7) days. They determined the mean period of ordinary superhumps 0.057203(10) days and constructed an (O-C) diagram of the positions of superhumps maxima suggesting their period variations (Fig. 47 of their work).

2. Photometry of the superoutburst

2.1. Light curve

Most of our $UBV(RI)_C$ CCD observations were taken with the SBIG ST10-XME camera mounted in the Newton focus of the 0.5m (f/5) reflector at the Stará Lesná observatory. Further CCD observations were taken with the Apogee-47p and Pictor-416 cameras mounted in the Cassegrain focus of the 0.6m (f/12.5) reflector and 0.5m Maksutov (f/4.0) telescope at the Crimean Laboratory of the Sternberg Astronomical Institute. We also used the 0.6m telescope Zeiss-600 of the Terskol Observatory (in Caucasus) equipped with a CCD camera (the PixelVision Vienna with a 1024x1024 array and pixel size 24 micron). The Maxim DL4 package and the special software written by V. Goranskij were used for the processing of the CCD frames.

We determined the $UBVR$ magnitudes of the star HD 12137 designated as "1" in Fig. 1, which is the brightest star in our frames, using the photoelectric photometer with photomultiplier Hamamatsu R 2949S in combination with the standard $UBVR$-filters, mounted in the Cassegrain focus of the 0.6m (f/12.5) reflector of the Stará Lesná Observatory. The standard procedure of the differential photometry was applied and HD 12131 was used as a comparison star. Its reliable magnitudes were published by Kornilov et al. (1991).

Table 1. The V magnitude and colour indices of the comparison stars.

Star	V	$U - B$	$B - V$	$V - R_C$	$R_C - I_C$	Sp
1	7.662	0.772	1.004	0.492	0.458	G9 III
±	0.005	0.004	0.006	0.005	-	
2	12.985	0.117	0.549	0.334	0.318	F9 III
±	0.010	0.009	0.013	0.013	0.011	
3	12.203	0.371	0.821	0.408	0.423	G9 V
±	0.007	0.008	0.010	0.009	0.011	
4	12.078	0.483	0.926	0.495	0.502	K2 V
±	0.003	0.008	0.008	0.005	0.012	

HD 12131 is situated only 18.6' north of the region under investigation. The magnitudes of the stars 2 – 4 (see Fig. 1) were found relatively to the star "1"
Figure 1. The comparison stars around V466 And, used for our CCD photometry.

in the CCD-frames made with a number of short exposures in order to disable the overflow for this bright star. Only the highest photometric quality nights were used for all these measurements. The data are presented in Table 1. We determined the spectral types of the comparison stars using their color indices and the standard $(U - B, B - V)$ diagram.

Due to the fact that the observations were obtained by different instruments, it was necessary to reduce them into one system ("z"), using the linear shifts. Their values are presented in Table 2.

Our $UBV(RI)_C$ observations of V466 And during its superoutburst and decline were obtained in 34 nights between Sept. 2 and Nov. 18, 2008. Brief information about the observations is presented in Table 3: JD, the average magnitude in each band during the night, the number of frames and the combination of the telescope and CCD-camera, denoted by marks "a, c, s, t, z" and explained in Table 2. The same marks are used in the tables of observations.

All our $UBV(RI)_C$ observations are displayed as follows: U in Table 7, B in Table 8, V in Table 9, R_C in Table 10 and I_C in Table 11. In the case of a good accuracy of individual measurements, they are presented with the JD in

Table 2. The magnitude correction for the standard sytem of observations.

mark	U	B	V	R_C	I_C	Location	Remarks
z	0	0	0	0	-	Stará Lesná	60-cm,phe UBVRc
s	-0.18	+0.21	-0.10	0	0	Stará Lesná	50-cm,CCD ST-10XME

a	-	-	-0.10	0	-	Crimea	50-cm, CCD Pic-416
c	0	+0.18	-0.10	0	-	Crimea	60-cm, CCD Ap-47p

four decimal numbers. In opposite case, the measurements are presented with the JD in two decimal numbers. In this case, the magnitude of a variable star is the mean value obtained as a result of combining a few CCD-images. The total number of summarized frames is given in Table 3.

The R_C, V light curves and $B - V$ and $V - R_C$ colour indices curves of V466 And are shown in Fig. 2. The R_C and V light curves exhibit the primary decline for $\approx 2.5 - 3$ mag. A similar decline is observed in all WZ Sge-type DNe. Nevertheless, in a few objects the short-time decline for a few magnitudes, followed by an increase to the previous brightness, was detected ("dip", see Table 5).

The fast decline of the brightness (> 1 mag/day) of V466 And occurred during the JD 2454733 – 736, 25 days after the beginning of the superoutburst. In Nova Tri 2008, the fast decline of brightness occurred 28 days after the beginning of the superoutburst (Chochol et al., 2009). The fast decline of AL Com (see Table 5) started 40 days after the beginning of the superoutburst (Patterson et al., 1996) detected in 1995. But the superoutburst amplitude of this object was higher than in nova Tri 2008 and V466 And. In SDSS J102146.44+234926.3, the fast decline started 20 days after the beginning of superoutburst, detected in 2007 (Pavlenko, 2007, Uemura et al., 2008). For SW UMa (an SU UMa type object), the fast decline occurred only 15 days after beginning of the superoutburst, as observed in 1995 (Burleigh et al., 2001) or 2000 (Pavlenko et al., 2000).

2.2. Colour - colour diagrams

The two-colour $(U - B, B - V)$ diagram of V466 And and 30 surrounding stars, detected in the same CCD images, is presented in Fig. 3. The direction of interstellar reddening is indicated by an arrow. It is obvious that the surrounding stars are not influenced by an interstellar extinction. Therefore, it is very probable that the light of the dwarf nova itself is not reddened, too. The corresponding data for these stars are presented in Table 4.

The celestial coordinates of the stars were derived using the MaxPoint package and USNO-A2.0 catalog with mean error of 0.4". The data in the table are arranged according to increasing right ascension.

Fig. 4 displays the evolution of V466 And in a two-colour $(U - B, B - V)$ diagram in a large scale. At the date of discovery, the object was located on the blackbody temperature sequence corresponding to the temperature of about 12000 K.

Thereafter, the object moved along the blackbody sequence towards the lower temperatures and reached 10000 K. The decrease of temperature is seen also in Fig. 2: during the brightness decline, the reddening of the colour-indices $B - V$ and $V - R_C$ was detected.
Figure 3. The two-colour $(U - B, B - V)$ diagram. The dwarf and giant sequences are plotted with the solid and dot-dashed lines, respectively. The colour indices of black bodies are shown by crosses and a dashed line. Filled diamonds correspond to V466 And, filled circles – to the position of the field stars.
Figure 4. The detail of the two-colour $(U - B, B - V)$ diagram. The evolution of the object on the black body temperature scale is depicted. Numbers near the observational points give the days after outburst, which occurred on JD=2454711.
Figure 5. The track of V466 And in the two-colour $(B - V, V - R_C)$ diagram. The main sequence, with designation of spectral types, is represented by a solid line.

The position of a very blue stellar object FBS B 224, with the strong UV-excess (Mickaelian & Gigoyan, 2006), found in the field of V466 And, is marked in Figs. 3 and 4, too.

Temperature decrease of the object during the superoutburst is indicated also in the two-colour $(B - V, V - R_C)$ diagram, presented in Fig. 5. A strange behaviour of the track after the day 22 of the superoutburst was caused by an increase of the strength of the H_α emission.

2.3. Early, ordinary and late superhumps

A Fourier period analysis of our BVR_C observations, after removal of the declining trend of the superoutburst light curve, revealed the presence of early, ordinary and late superhumps and enabled us to determine their periods. The folded light curves of V466 And, phased with the periods: $0.^d056383$ for early superhumps, $0.^d05713$ for ordinary superhumps and $0.^d056$ for late superhumps, are presented in Figs. 6 – 11. Because the amplitude of this variability does not depend on the passband, we present their summarized phase light curves in BVR_C-bands.

In Fig. 6 (days 1–3 after outburst (AO)), the early superhumps are presented in the form of a double wave with the amplitude of 0.07 mag. There is a large scatter of the data.

Fig. 7 (days 4–7 AO) shows the continuation of the early superhump stage, but the double wave is expressed less clearly. Its amplitude decreased to ~ 0.05 mag.

Fig. 8 (days 8–9 AO) exhibits a weak double wave with the amplitude < 0.02 mag, hardly visible in scattered data.

phase
Figure 11. The late superhumps: their period and amplitude are very unstable.

Fig. 9 (day 11 AO) presents variations at the moment (JD 2454721) when the ordinary superhumps probably "turned on". The amplitude increased to ~ 0.07 mag, but the slight "phantom" of a double wave is still visible.

Fig. 10 (days 12–23 AO) shows the ordinary superhumps with the large amplitude ~ 0.2 mag and period of $0.^{d}05713$.

Fig. 11 (days 24–33 AO) presents late superhumps with an unstable period and amplitude. The average value of the period is $0.^{d}056$, while the mean amplitude is smaller than 0.02 mag. There is only one wave during the period. The scatter of the data is very large.

The multicolour light curves of ordinary superhumps taken on the day 13 AO (JD 2454723) are shown in Fig. 12.

The early superhumps are a unique feature of WZ Sge-type stars. They appear near the maximum magnitude of superoutburst and have periods almost identical to the orbital one. Osaki and Meyer (2002) suggested that a double peaked profile of early superhumps is manifestation of the tidal 2:1 resonance in accretion disks of binary systems with extremely low mass ratios. Early superhumps can be explained by a two-armed spiral pattern of tidal dissipation generated by the 2:1 resonance, first proposed by Lin and Papaloizou (1979).

The ordinary (common) superhumps, with a single peak profile, appear during the plateau of superoutburst of WZ Sge-type stars. Their periods are a few percent longer than the orbital period. The ordinary superhumps can be explained by the thermal tidal instability model of an accretion disk (Osaki, 1989; Whitehurst, 1988). The presence of the tidal 3:1 resonance in the disk (with the radius smaller than the 2:1 resonance radius) results in the formation of an eccentric outer ring undergoing apsidal precession with a period appreciably longer than the orbital one. The beating of the orbital and precessional periods cause periodic variations, identified as superhumps. This model is supported by numerical simulations (Bisikalo et al., 2005; Kaigorodov et al., 2006; Smith et al., 2007). However, Smak (2009) pointed out that the tidal model fails to reproduce the amplitudes of superhumps. In his new interpretation of superhumps, periodically variable irradiation of the secondary component results in a strongly modulated mass outflow. Superhumps are then due to enhanced dissipation of the kinetic energy of the stream.

The late superhumps appear several days after the rapid decline from the plateau of a superoutburst and may continue for several hundred cycles after the end of the superoutburst. The recent paper of Kato et al. (2009a), devoted to the period variations of superhumps in an SU UMa-type dwarf novae, presented data and analysis of observations about a hundred SU UMa and WZ Sge stars. It contains a description and review of some models and theories of outbursts of these systems. According to Kato et al. (2008), the late superhumps are proposed to originate in the precessing eccentric disk near the tidal truncation. The eccentric disk slowly expands during the decline of the superoutburst and finally reaches the tidal truncation, where the period is stabilized. It can be a natural extension of the explanation of late superhumps in WZ Sge-stars.
Figure 12. $UBVR_c$ light curves of V466 And on Sept. 13, 2008 (JD 2454723). The ordinary superhumps are clearly visible. Open circles – photometry from Stará Lesná, filled circles – photometry from Terskol.

In V466 And the early superhumps with the stable period of $0.^d056383$ and the form of a double wave were observed in days 3–11 AO. As seen in Fig. 13, the day 11 AO was the day of transition to the ordinary superhumps. The ordinary superhumps with the stable period of $0.^d05713$ and the form of a single wave were observed in the days 13–23 AO (Fig. 14). In days 24–33 AO the late superhumps with an unstable period about of 0.056 days and a small amplitude were detected (Fig. 11). The period of late superhumps in V466 And is smaller than that of ordinary superhumps. The late superhumps in WZ Sge-type stars have usually longer periods than the ordinary superhumps (see Kato et al., 2009a). The shorter period of the late superhumps in V466 And may be a sign of shrinking of the accretion disc.

3. WZ Sge-type dwarf novae and concluding remarks

Our photometric observations allow to classify V466 And as a dwarf nova of the WZ Sge-type. Another object of this type – nova Tri 2008 = CSS081026:023839 +355648 (or OT J023839.1 + 355648) has a very similar light curve and the colour-colour diagrams (Chochol et al., 2009). The early superhumps in V466 And are clearly expressed and a double-wave is seen better than in CSS081026. Both systems did not exhibit any rebrightenings. But in Nova Tri 2008 a sudden increase of activity with the amplitude of ∼1 mag was detected in quiescence (Chochol et al., 2009). V466 And in quiescence is not accessible to our telescopes facilities, but we could not miss any $2 - 3$ mag rebrightening. WZ Sge itself had 13 rebrightenings and SDSS J080434.20+510349.2, another new WZ Sge-type star, showed 11 rebrightenings of a decreasing amplitude with the $2.^d5$ cycle (Pavlenko, 2007; Pavlenko et al., 2007; Kato et al., 2009b).

Due to the fact that we know only about 30 WZ Sge-type stars, detailed investigations of each object are very important. It helps to accumulate more data for a particular object as well as to increase the statistical data for all objects of this type. This investigation will help to understand the physical processes occurring in WZ Sge-type stars. A list of WZ Sge-type stars and suspected ones, with their main characteristics, is presented in Tables 5 and 6. The periods of ordinary superhumps P_{sh} were used in these tables (see Kato et al., (2009a)). For known values of orbital and superhump periods, we calculated the superhump period excess applying the well known relation $\epsilon = P_{sh}/P_{orb}$–1. Using the data from Tables 5 and 6, we found the mean value of a superhump period excess for WZ Sge-type objects as ϵ=0.019±0.003. In the case that either orbital or ordinary superhumps periods were not published, we appended them to Tables 5 and 6, using the relation metioned above. A more explicative table of candidates for WZ Sge-type dwarf novae and related systems was presented by Kato et al. (2001b).
Figure 13. The phase evolution of early superhumps. The maxima of superhumps (days 1-9 AO) follow the ephemeris: $JD_{max} = 2454711.4688 + 0.056383 \cdot E$. The day 11 AO was the day of transition from the early to the ordinary superhumps.
Figure 14. The phase light curve of ordinary superhumps. The maxima of superhumps (days 13-23 AO) follow the ephemeris: $JD_{max} = 2454723.5020 + 0.05713 \cdot E$ (see also Fig.12).

We consider investigating photo-plate archives to find the possible super-outbursts of WZ Sge-type stars with the aim to determine their outburst and rebrightenings cycles. This study could test the idea of accumulation of the matter in the outer disc (Kato et al., 1998) that can cause rebrightenings.

In support of this suggestion, Uemura et al. (2008) discussed a superoutburst and a long rebrightening of the new WZ Sge-type system SDSS J102146.44 +234926.3 (J1021 in Table 5), which occurred in November 2006.

This object was observed very thoroughly in the optical region, R_C and for the first time also in J and K_s bands, using the 1.5-m KANATA telescope. J1021 showed a strong activity in the K_s-band and IR superhumps. They indicate the presence of additional matter in outer parts of the accretion disc.

Table 11. I_C magnitudes of V466 And. The symbols "s" is explained in Table 2. $\mathrm{JD}_{hel} = \mathrm{JD}^* + 2\,454\,700$.
